Abstract

The basic motivation of this paper is to apply the Horner’s method to perform the steps in Newton and improved Newton methods for approximating the Solution of Barker’s equation in parabolic motion.

A simple starting value for the iterative solutions is suggested. Some Numerical applications are presented and show that only little iteration is required to obtain approximate solutions which are found to be accurate and efficient.

Keywords: Barker’s equation, Horner’s method, Newton method, improved Newton method.

1. Introduction

Many instances of parabolic orbits occur in the solar system, especially some smaller comments. Also, the intermediate portion of interplanetary mission may be a heliocentric parabola [2].

For the parabolic motion, the basic equation to be solved is known as Barker’s equation which is the relation between the true anomaly \( V \) and the time \( t \) for parabolic motion and is given as [5]:

\[
2 \pi (t - \tau) = \tan \frac{V}{2} + \tan \frac{3V}{2} \tag{1}
\]

where \( \pi = \frac{\mu}{p^3}, \) \( \mu \) is the gravitational constant, and \( p \) is twice the pericenter distance \( (p = \frac{2\pi}{n}, n \) is the mean motion), \( \tau \) is the time of pericenter passage. The problem is to find the true anomaly \( V \), where \( \tau, t, \pi \) are given.

Eq.(1) can be rearranged as:

\[
\tan \frac{V}{2} + 3 \tan \frac{V}{2} - 6\pi (t - \tau) = 0 \tag{2}
\]

There are many methods to solve eq (2) [5-7], in this paper both Newton Horner and improved
Newton Horner methods are applied to solve eq (2).

**Descartes Rule of signs to Barker's equation**

The expected roots can be examined using Descarte’s Rule of signs for polynomials of the form

\[ f(x) = 0. \]

Let \( f(x) \) be a polynomial with real coefficients then:

(i) the number of positive zeros of \( f \) is either equal to the number of variations in sign of \( f(x) \) or less than this by an even number.

(ii) The number of negative real zeros of \( f \) is either equal to the number of variations in sign of \( f(-x) \) or less than this by an even number.

Note that Barker’s equation is a kind of special cubic equation in \( \tan \frac{3V}{2} \).

Hence eq(2) can be written a

\[ x^3 + 3x - b = 0 \]

where \( b = 6\bar{n}(t - \tau) \).

Now, using (i), \( x^3 + 3x - b = 0 \) + to -

There is one sign change so we have at most one positive real root (note \( b > 0 \)).

Using (ii), \((-x^3) + 3(-x) - b = 0\), we have zero sign changes so no negative real roots.

Our conclusion is that eq.(3) has one real positive root and two complex conjugate roots.

We need to solve for the real root.

### Module of Horner’s Method

**Horner’s Method for polynomial Evaluation**

Assume that

\[ f(x) = a_n x^n + a_{n-1} x^{n-1} + \ldots + a_1 x + a_0 \]

\( \ldots(4) \)

and \( x = z \) is a number for which \( f(z) \) is to be evaluated. Then \( f(z) \) can be computed recursively as follows:

set \( b_n = a_n \) and \( b_k = a_k + z \ b_{k+1} \) for \( k = n-1, n-2, \ldots, 2, 1, 0 \) then \( f(z) = b_0 \).

#### 3.2. Horner’s Method for First Derivatives

Assume that

\[ f(x) = a_n x^n + a_{n-1} x^{n-1} + \ldots + a_1 x + a_0 \]

and \( x = z \) is a number for which \( f(z) \) and \( f'(z) \) are to be evaluated. We have already seen that \( f(z) = b_0 \) can be computed recursively as follows \( b_n = a_n \) and

\( b_k = a_k + z \ b_{k+1} \) for \( k = n-1, n-2, \ldots, 2, 1, 0 \)

Now, \( f'(z) \) can be computed recursively as follows \( c_n = b_n \) and \( c_k = b_k + z \ c_{k+1} \) for \( k = n-1, n-2, \ldots, 2, 1 \). Then \( f'(z) = c_1 \).

#### 3.3. Horner’s Method for Second Derivatives

Assume that

\[ f(x) = a_n x^n + a_{n-1} x^{n-1} + \ldots + a_1 x + a_0 \]

and \( x = z \) is a number for which \( f(z) \), \( f'(z) \) and \( f''(z) \)
Approximate Solutions of Barker Equation in Parabolic Orbits

are to be evaluated. We have already seen that \( f(z) = b_0 \) and \( f'(z) = c_1 \) can be computed recursively as follows:

\[
b_k = a_k + z \quad b_{k+1} \quad \text{for} \quad k = n-1, n-2, ..., 2, 1, 0
\]

\[
c_n = b_n \quad \text{and} \quad c_k = b_k + z \quad c_{k+1} \quad \text{for} \quad k = n-1, n-2, ..., 2, 1.
\]

Now, \( f''(z) \) can be computed recursively as follows:

\[
d_n = c_n \quad \text{and} \quad d_k = c_k + z \quad d_{k+1} \quad \text{for} \quad n-1, n-2, ..., 2.
\]

Then, \( f''(z) = 2!d_2 \).

Remarks:

Assume that the coefficients \( \{a_{i,j}\}_{i,j} \) of Barker’s equation, eq.(3), of degree 3 are stored in the first row of the matrix \( [a_{i,j}]_{3x4} \). Then the polynomial \( f(x) \) can be written in the form \( f[x] = \sum_{i=0}^{3} a_{i,j} x^i \).

Given the value \( x = z \), the subroutine for computing all the derivatives \( \{f^{(i)}[z]\}_{i=0}^{5} \) is

\[
[a_{i,4}] = [a[i-1,4]] \quad \text{for} \quad i = 2, 3, 4, 5
\]

\[
[a_{i,k}] = a_{i-1,k} + z a_{i-1,k+1} \quad \text{for} \quad k = 3, 2, 1; \quad i = 2, 3, 4, 5
\]

and

\[
f^{(i)}[z] = i!a_{i,2+i} \quad \text{for} \quad i = 0, 1, 2, 3.
\]

Therefore, the matrix \( [a_{i,j}]_{3x4} \) can be constructed as follows:

Assume that \( f(x) \) is a polynomial of degree \( n \geq 2 \) and there exists a number \( x \in (a, b) \), where \( f(x) = 0 \). If \( f'(x) \neq 0 \), then there exists a \( \delta > 0 \) such that the sequence \( \{x_k\}_{k=0}^{\infty} \) defined by the Newton-Raphson iteration formula

\[
x_{k+1} = x_k - \frac{f(x_k)}{f'(x_k)}, \quad k = 0, 1, ...
\]

will converge to \( x \) for any initial approximation \( x_0 \in \{x - \delta, x + \delta\} \), [3].

Now, the recursive formula of Newton-Horner iteration can be adapted to compute \( f'(x_k) \) and \( f''(x_k) \) such that \( f(x_k) = b_0 \) and \( f'(x_k) = c_{k,1} \) and the resulting Newton-Horner iteration formula will be

\[
x_{k+1} = x_k - \frac{b_0}{c_{k,1}} \quad \text{for} \quad k = 0, 1, ...
\]

where \( x_0 \) is an initial guess.

5. Improved Newton-Horner Method

A modified Newton’s method can be developed by keeping the second order terms in Taylor series...
expansion and the following result will be

\[ x_{k+1} = x_k - \frac{f(x_k)}{f'(x_k)} \left[ 1 + \frac{1}{2} \frac{f(x_k) f''(x_k)}{(f'(x_k))^2} \right] \]

Now, the recursive formula of improved Newton-Horner iteration can be adopted to compute \( f(r_k) \), \( f'(r_k) \) and \( f''(k) \) as follows

\[ f\left(x_k\right) = b_{k,0}, \quad f'\left(x_k\right) = c_{k,1} \quad \text{and} \quad f''\left(x_k\right) = 2d_{k,2} \]

Hence, the resulting improved Newton-Horner iteration formula will be

\[ x_{k+1} = x_k - \frac{b_{k,0}}{c_{k,1}} \left[ 1 + \frac{b_{k,0}}{c_{k,1}} d_{k,2} \right], \quad k = 0, 1, \ldots \]

or

\[ x_{k+1} = x_k - \frac{b_{k,0}}{c_{k,1}} \left[ 1 + \frac{b_{k,0}}{c_{k,1}} d_{k,2} \right], \quad k = 0, 1, \ldots \] (6)

and \( x_0 \) is an initial guess.

6. Convergence of Newton-Horner Method

In this section we will show a criterion of convergence of Newton-Horner method. The algorithm

\[ x_{k+1} = x_k - \frac{b_{k,0}}{c_{k,1}} \]

is of the form \( x_{k+1} = g(x_k) \). Successive iterations converge if \( |g'(x_k)| < 1 \).

Since

\[ g(x) = x - \frac{b_k}{c_i}, \quad \text{Therefore} \]

\[ g'(x) = 1 - \frac{c_i b_k' - b_k c_i'}{c_i}, \quad \text{(note that} \quad b_k = f(x) \text{ and} \]

\[ c_i = f'(x), \quad \text{since} \quad b_k' = c_1, \quad \text{then} \quad g'(x) = \frac{c_i b_k' - b_k c_i'}{c_i} = \frac{b_k c_i'}{c_i} \]

Hence if \( \left| \frac{b_k c_i'}{c_i} \right| < 1 \) an interval about the root \( x^* \), the method will converge for any initial value in the interval.

In Barker’s equation, we have

\[ b_k = x^3 + 3x - b, \quad c_1 = 3x^2 + 3, \quad \text{so:} \]

\[ (d_0 = f''(x)) \quad \text{so,} \]

\[ \left| \frac{b_k c_i'}{c_i} \right| = \left| \frac{c_i b_k' - b_k c_i'}{c_i} \right| = \left| \frac{1}{3} (x' + 3x - bx^2 + 3) \right| < 1 \]

for convergence if

\[ x^* = \frac{b}{5} \Rightarrow g'(x) = x^2 + 3x - bx^2 + 3 = 0.1900621456 < 1 \]

if

\[ x^* = \frac{b}{4} \Rightarrow g'(x) = x^2 + 3x - bx^2 + 3 = 0.0812937789 < 1 \]

if

\[ x^* = \frac{b}{3} \Rightarrow g'(x) = x^2 + 3x - bx^2 + 3 = 0.1173861768 < 1 \]

if

\[ x^* = \frac{b}{2} \Rightarrow g'(x) = x^2 + 3x - bx^2 + 3 = 0.41286829 < 1 \]
7. Convergence of Improved Newton-Horner Method

The algorithm
\[ x_{k+1} = x_k - \frac{b_k}{c_k} \left[ 1 + \frac{b_k d_{k+1}}{(c_{k+1})^2} \right] \quad \text{for } k = 0, 1, \ldots \]
is of the form \( x_{k+1} = g(x_k) \). Successive iterations converge if \( |g'(x_k)| < 1 \)
\[
g(x) = x - \frac{b_j}{c_j} \left[ 1 + \frac{b_j d_{j+1}}{c_{j+1}} \right] \quad \text{therefore} \quad g'(x) = \frac{1}{2} \left( \frac{b_j}{c_j} \right) \left( -0.5 c_j d'_j + 3 d'_j \right)
\]

Numerical Examples

Here, Barker’s equation is solved using both Newton-Horner and improved Newton-Horner methods.

Consider eq.(3), where \((t - \tau) = 1.2025 \text{ TU} \) (time unit) in a parabolic orbit where \( p = 2 \text{ AU} \) (angular distance unit) and \( \mu = 1 \).

Then
\[
\tilde{\pi} = \frac{\mu}{p^2} = \frac{1}{2^3} = \frac{1}{2\sqrt{2}}
\]
and hence \( b = 6\tilde{\pi} (t - \tau) = 2.55088771 \)

We use Newton-Horner method to solve eq.(3) to get:

\[
\begin{bmatrix}
-2.55088771 & 3 & 0 & 1 \\
-2.55088771 + 3x_i & x_i & 1 \\
3 + 3x^2 & 2x_i & 1 \\
0 & 0 & 6x_i & 1 \\
0 & 0 & 0 & 1
\end{bmatrix}^k = \begin{bmatrix}
0.1049725343 & 0.066333 & 0.0 & 0.0  \\
0.0 & 0.021058 & 0.0 & 0.0  \\
0.0 & 0.0 & 0.0 & 0.0  \\
0.0 & 0.0 & 0.0 & 0.0
\end{bmatrix}
\]

In this paper, a simple starting value is considered for the proposed methods of Barker’s equation is presented to be

\[
x_0 = \frac{b}{4} = 0.6377213 \quad \text{as an initial guess yields}
\]

\[
\begin{bmatrix}
-2.55088771 & 3 & 0 & 1 \\
-0.37836728 & 3.40668925 & 0.63772193 & 1 \\
0 & 4.22006770 & 1.27544385 & 1 \\
0 & 0 & 3.826331561 & 1 \\
0 & 0 & 0 & 1
\end{bmatrix}^k = \begin{bmatrix}
0.0 & 0.0 & 0.0 & 0.0  \\
0.0 & 0.0 & 0.0 & 0.0  \\
0.0 & 0.0 & 0.0 & 0.0  \\
0.0 & 0.0 & 0.0 & 0.0
\end{bmatrix}
\]

Here
\[
\begin{bmatrix}
-2.55088771 & 3 & 0 & 1 \\
-0.37836728 & 3.40668925 & 0.63772193 & 1 \\
0 & 4.22006770 & 1.27544385 & 1 \\
0 & 0 & 3.826331561 & 1 \\
0 & 0 & 0 & 1
\end{bmatrix}^{(1)} = \begin{bmatrix}
0.1049725343 & 0.066333 & 0.0 & 0.0  \\
0.0 & 0.021058 & 0.0 & 0.0  \\
0.0 & 0.0 & 0.0 & 0.0  \\
0.0 & 0.0 & 0.0 & 0.0
\end{bmatrix}
\]

\[
\begin{bmatrix}
-2.55088771 & 3 & 0 & 1 \\
-0.37836728 & 3.40668925 & 0.63772193 & 1 \\
0 & 4.22006770 & 1.27544385 & 1 \\
0 & 0 & 3.826331561 & 1 \\
0 & 0 & 0 & 1
\end{bmatrix}^{(2)} = \begin{bmatrix}
0.0565733356 & 0.0 & 0.066333 & 0.0  \\
0.0 & 0.0 & 0.0 & 0.0  \\
0.0 & 0.0 & 0.0 & 0.0  \\
0.0 & 0.0 & 0.0 & 0.0
\end{bmatrix}
\]

\[
x_1 = \frac{b}{4} = 0.6377213 \quad \text{to get:}
\]

\[
\begin{bmatrix}
-2.55088771 & 3 & 0 & 1 \\
-0.37836728 & 3.40668925 & 0.63772193 & 1 \\
0 & 4.22006770 & 1.27544385 & 1 \\
0 & 0 & 3.826331561 & 1 \\
0 & 0 & 0 & 1
\end{bmatrix}^{(3)} = \begin{bmatrix}
0.0565733356 & 0.0 & 0.066333 & 0.0  \\
0.0 & 0.0 & 0.0 & 0.0  \\
0.0 & 0.0 & 0.0 & 0.0  \\
0.0 & 0.0 & 0.0 & 0.0
\end{bmatrix}
\]
Approximate Solutions of Barker Equation in Parabolic Orbits

\[ a^{(0)} = c_{0,1} = f'(x_0) = 4.40668925 \]
\[ a^{(1)} = d_{0,2} = f''(x_0) = 1.91316578 \]

Hence, the results are:

Newton-Horner:
\[ x_1 = x_0 - \frac{b_{0,0}}{c_{0,1}} = 0.72738364 \]

Improved Newton-Horner:
\[ x_i = x_0 - \frac{b_{0,0}}{c_{0,1}}(1 + \frac{b_{0,0}d_{0,2}}{(c_{0,1})^2}) = 0.72373930 \]

Then the iterations of Barker’s equation, (1) will converge to the root \( x = 0.72386802 \).

Table (1-4): show the number of iterations required for convergence of Barker’s equation (1) using different initial guesses.

In order to find the true anomaly \( \nu \), we use
\[ x = \tan^{-1} \frac{\nu}{2} = \tan^{-1} \frac{7179915}{1153} \]

Discussion

Newton-Horner is improved and applied to find the solution of Barker’s equation in parabolic motion. Some starting values was suggested, convergence had been demonstrated from the suggested starting values. It was found that the starting value \( x_0 = \frac{3\pi(t-\tau)}{2} \), produced the lowest iteration number. The processes is repeated until the following convergence test is satisfied \( |f(x)| < \varepsilon \) where \( \varepsilon \) is the convergence tolerance, here \( \varepsilon = 10^{-6} \).

The improved Newton-Horner’s method usually converges more rapidly than Newton-Horner and should make it the preferred method for the solution of Barker’s equation.
